Introduction
Beginning in 2019, under the guidance and funding provided by the United States Geological Survey, The Great Lakes Mapping Coalition (award G20AC00461), the New York State Museum - Geological Survey began a statewide effort to conduct geologic mapping of bedrock elevations throughout New York. Niagara County, of northwestern New York, lies within the Erie-Ontario Lowlands physiographic province. The county is north of Erie County and west of Orleans and Genesee Counties, with Canada’s Ontario Province to the west. Niagara County is also bordered by Lake Ontario to the north. Surficial and subsurface bedrock point data and maps were compiled from publicly available sources, vetted, and organized into a comprehensive geospatial database. A technical workflow was developed to categorize the overall geology and differentiate between the underlying bedrock and overlying unconsolidated sediments. The resulting bedrock elevation map provides a detailed representation of bedrock topography across Niagara County. This map is useful for various applications, including geological studies, engineering and construction, natural resource management (such as water or mineral resources), and environmental studies.

Methodology
A total of 437 bedrock control points were used to delineate the bedrock topography in Niagara County. These points consisted of 114 water wells, 159 thruway engineering boreholes, 139 bedrock outcrops, and 25 waterfall locations. These data were compiled from a variety of public sources and imported into ESRI ArcMap 10.8 software platform. Ground surface elevations for all control points were extracted from a digital elevation model (DEM) which was resampled to match a 1-meter LiDAR DEM cell size. Bedrock elevations were calculated at each location by subtracting the depth-to-bedrock from the ground surface elevation. Fifty-foot bedrock elevation contours were automatically generated and manually refined through a multi-step quality control process to resolve any interpolation errors. The finalized contours were converted into a 1-meter raster, using the “Topo toRaster” tool, that represents county-wide bedrock topography.

Summary
The New York State Museum – Geological Survey has developed a detailed Bedrock Topography Map for Niagara County. This map represents a compilation of various surficial and subsurface bedrock data sources, analytical methods, and quality control procedures. The resulting bedrock elevations reveal a range of distinct geological features including a variety of Paleozoic bedrock erosional profiles, and evidence of past glaciation. These characteristics are likely the result of a variety of processes including bedrock stratigraphy, structural deformation, and erosional processes such as past glaciation and fluvial geomorphology.

This map is significant for applications in geological research, engineering, natural resource management, and environmental studies. Continued research and work on subsurface geology will provide additional data and insight and enhance the geologic framework of bedrock geology throughout New York State.
